BRAIN Playbook

How to read BRAIN's live market data for 15-minute Bitcoin and XRP prediction-market rounds.

EDITION 2 · OCTOBER 2026 · BRAINSWATCH.COM

Information and education only. Not financial advice. BRAIN gathers and displays market data; it never tells anyone to trade or what to do with their money.

START HERE

What BRAIN is (and isn't)

BRAIN is an information service. Its software watches public market data around the clock, measures it, and shows you what it sees, live.

What BRAIN does

Gathers prices, trades and order books from the exchanges that matter, plus the prediction market's own prices.
Shows its readings live and grades every one against how the round really settled.

What BRAIN doesn't do

It doesn't give financial advice or tell anyone to buy, sell, hold or place money anywhere.
It doesn't know your finances and doesn't trade for members. Every decision is yours.

How a 15-minute round works

PIECE	WHAT IT MEANS
The line (target)	The price the market sets when the round opens. The question is simply: will the price be above or below this line when the round ends?
UP / DOWN	**UP** = settles above the line. **DOWN** = settles below it.
The market %	The market's own price for a side, read as the crowd's odds. 72% on UP means UP costs about 72¢ and pays $1 if right.
Settlement	Rounds settle on an independent index of major exchanges, **averaged over the last 60 seconds**, so a spike in the final seconds barely moves it.
Payout	A correct side pays $1 per contract at settlement; a wrong side pays $0. Buying at 72¢ means 28¢ profit if right and 72¢ lost if wrong, before fees.
Fees	The market charges a trading fee, largest near 50¢ and smallest near 1¢ or 99¢. Fees mean a side can be right most of the time and still lose money overall.
Before the end	Prices move all round. A position can be sold before settlement at whatever the market is paying at that moment, which may be more or less than it cost.
The clock	15 minutes per round. BRAIN reads it at the 4:00 and 8:00 marks and counts down continuously.

Prediction markets carry a high risk of loss. Everything in this guide explains what BRAIN's screens show. None of it is a suggestion to trade.

THE CORE READING

The calls

A "call" is BRAIN's model reading of which side the data leans toward at a fixed moment. It's a measurement, not an instruction.

Early · 4:00

The first reading, 4 minutes in. More time left means more can change.

Sealed · 8:00

The main reading, locked at 8 minutes. It's the one tracked hardest in the record.

Late call

Only when the sealed reading sat out a coin flip and price later clearly decided.

Two numbers on every call

LINE IN THE BOX	WHAT IT TELLS YOU
BRAIN confidence: 84%	How strongly BRAIN's own models lean to that side at the lock.
Market at lock: 72%	What the market was charging for that side at the exact moment the call locked. Comparing the two shows whether BRAIN and the crowd agreed.
Market agrees · 70%	The market's price for that side right now. "Agrees" means the market still favors BRAIN's side; "disagrees" means it has swung the other way.

Confidence tiers

TIER	CONFIDENCE	NOTES
SUPER	Highest	The strongest readings, backed by a strong record from similar rounds.
GOOD	Clear lean	A clear lean. A choppy round or mixed signals can lower a reading's tier.
WEAK	Close	A lean, but close. This is where most misses happen (see the scorecard on page 5).

Tags you may see

80% SETUP: the round matches a pattern that scored 80%+ on rounds it was never built from. **REVERSAL**: the reading sides with the underdog because several signals point to a turn. **Top traders agree**: verified high-record traders were on the same side (sealed call only, never changes the direction). **Held the early call**: the 8:00 reading kept the 4:00 side because switching at that confidence has lost more often than it won (page 4).

UNDER THE HOOD

How BRAIN learns

BRAIN doesn't just read the round in front of it. It checks how every past round from the same spot actually ended, wins and losses, and keeps updating.

Price-target history

At 4:00 and 8:00 BRAIN looks at where price sits against the line and what the market is doing, then checks how past rounds in a similar spot actually ended. The reason under the call shows it in plain words, e.g. *"38 of 45 rounds from this spot ended UP (84%) with the trend up."*

A few lucky rounds can't swing a reading on their own; it takes a real record.

Trend

BRAIN reads the short-term trend as **up**, **down** or flat.

If readings that go against a running trend keep losing, BRAIN learns that and leans with the trend instead.

Learning from losses

Recent rounds count more than older ones, so this week's misses reshape the next reading quickly.

It refreshes several times a day, and changes only go live after they prove themselves on rounds they were never built from.

Early vs sealed: the flip check

Sometimes the 8:00 reading disagrees with the 4:00 reading. BRAIN studies every past round where that happened and learns how sure the 8:00 reading has to be before switching sides has actually paid off. Below that level, the sealed reading **holds the early side** and says so on screen.

This rule is tested the same way and only used when it has produced more correct readings, not fewer.

BY THE NUMBERS

4:00 vs 8:00: the scorecard

How each reading has scored in BRAIN's backtest of 1,992 Bitcoin rounds over 21 days (October 2026), graded against how each round settled.

EARLY · 4:00

68.7%

right overall · side cost about 69¢ on average

SEALED · 8:00

78.4%

right overall · side cost about 78¢ on average

By confidence tier

TIER	EARLY 4:00	SEALED 8:00
SUPER	**86.1% (423 rounds)**	**89.4% (603 rounds)**
GOOD	70.2% (734)	78.7% (633)
WEAK	**57.1% (718)**	**68.2% (670)**

What the record shows

Later is more often right, but costs more. By 8:00 price has usually moved, so the 8:00 reading is right more often, but the market already prices that in. The leading side cost about 78¢ at 8:00 vs 69¢ at 4:00, so each correct reading is worth less.

Tier matters more than timing. A 4:00 SUPER reading (86.1%) has scored nearly as well as an 8:00 SUPER (89.4%), and far better than any WEAK reading.

WEAK is where the misses are. Close rounds stay close; 57–68% isn't far from a coin flip.

Fees change the picture. In the $100 simulation (page 9), after the market's fee and a cent of slippage, most readings came out near break-even. 4:00 SUPER readings were slightly positive (+0.7% per dollar).

Past and simulated results don't predict future results. These numbers update as the backtest reruns; the live record is always on the dashboard.

THE GAUGES

Reading the round

Around the calls, BRAIN shows the measurements that drive them.

Line crosses: how choppy the round is

CROSSES SO FAR	0	1	2	3	4+
Market favorite won at 8:00	**82.6%**	76.9%	70.9%	67.5%	**62.8%**

From BRAIN's 21-day backtest of 1,992 Bitcoin rounds (1-minute candles). Each extra cross has meant a less settled round. Box labels: CLEAN 0–1 · SOME CHOP 2 · CHOPPY 3+.

RSI (14): momentum

BRAIN shows RSI the way **TradingView** and **Webull** compute it, so it matches the charts you already use. The starred one is whichever has read rounds better lately.

METHOD	RSI ABOVE/BELOW 50 MATCHED THE ROUND AT 8:00	AT EXTREMES (70+ / 30−)
TradingView	73.2%	91.9% (160 rounds)
Webull	72.3%	85.0% (453 rounds)

By 8:00 price has often already moved, so RSI partly confirms the move rather than predicting it.

Projected settlement

In the final minute BRAIN averages the index second by second, the way the round settles, and shows what the remaining seconds would need to average to flip it.

Flip radar

A 0–99% estimate of how likely the round is to cross back to the other side.

Price-target history

At the bottom of each coin: the last three rounds whose line was this one or closest to it (within 5%), how each ended, and whether BRAIN's sealed reading matched.

LIVE ALERTS

Flip watch, sounds and voice

Alerts describe a change in the data the moment it happens.

Flip watch pills

After a confirmed flip, a slim pill floats at the top of the page:

YOU SEE	IT MEANS
▲ UP with call 74%	Price is moving the same way as the call.
▼ DOWN against call 53%	Price is moving against the call (amber text).
HOLDING	The market is back on the call's side.
TURNED	The market has turned clearly against the call.

Cash-out level note

When the called side reaches 90%+ on the market with 2+ minutes left, the voice says *"Some traders cash out here."* It describes the market; it's not a suggestion.

Late coin flip

With 3 minutes or less left and the market at 40–60%, BRAIN says the round is a real coin flip, and adds "it's flipping" if price just crossed the line.

Sounds and voices

Cash-register cha-ching	A whale **buy** just printed.
Double beep	A whale **sell** just printed.
Chime + spoken call	An early, sealed or late call just locked, with BRAIN's confidence and the market's price.
Voices	Ava, Jenny, Aria, Emma, Michelle, Tony (New York style) or Sarge (drill sergeant). Pick one in Sound settings; sound needs one tap to switch on in each browser session.

BIG MONEY

Whales, exchanges and Trader Radar

Not every big trade matters equally. BRAIN scores each one.

Exchange trust tiers

TIER	EXCHANGES	WHY
Index	The exchanges the settlement index is built from	They feed the index the round settles on, so their trades move the settlement price directly.
Big global	The largest global exchanges and futures markets	Lead price discovery but don't count toward settlement.
Low-trust	Dropped from BRAIN	Offshore venues with enforcement history or thin volume aren't read at all.

Whale impact score (0–100)

Each big trade is scored on how much it could actually move this round, not just its size. A large buy when the round is a toss-up and price sits right on the line scores high; the same buy when the market is already at 97% scores low.

After every alert BRAIN checks whether price really moved the whale's way and keeps a running hit rate, so the score's accuracy is measured, not assumed.

Trader Radar

Tracks positions that well-known prediction-market traders show publicly, only from accounts locked as the real ones. Lookalike names (M0GS, mogs_, letters from other alphabets) are ignored as impostors. Records are kept by round, hour, day and 7 days.

ACCOUNTABILITY

The record

Every reading is graded against how the round actually settled. Wins and losses both stay on the screen.

Streaks & scoreboard

The current run of right or wrong readings, the best and worst runs, today's record and the latest results as small circles.

Round history

Tap the badge at the top right for today, this week and all time: win rate per call, by tier, how readings did **with vs against the trend**, and every graded round.

Reading the result circles

Two things in one circle: the **color** is how the round ended (**green = UP**, **red = DOWN**), and the **letter** is whether BRAIN's reading was right: a white W when it was, an L in the circle's color when it wasn't.

W	Read DOWN, ended DOWN	W	Read UP, ended UP
L	Read DOWN, but ended UP	L	Read UP, but ended DOWN

The $100-a-trade example

To show what a reading's record looks like in dollars, BRAIN replays every graded call as if $100 had been placed at the market's price at the moment of the call, held to settlement, with the market's fee and a cent of slippage included.

This is a simulation. It uses past data, assumes fills at the price shown, and doesn't reflect real trading. Past and hypothetical results never predict future results, and nothing here suggests placing $100, or any amount, on anything.

The backtest

Several times a day BRAIN replays recent Bitcoin rounds to check which readings held up and where they lost, and refreshes what it has learned (page 4).

BEFORE YOU GO

Risk, and a quick glossary

Read this. BRAIN is an information and data service. Nothing in BRAIN or in this Playbook is financial, investment, trading, legal or tax advice, a recommendation, or an instruction to buy, sell, hold or trade anything, or to do anything with your money.

Calls, tiers, percentages, badges, alerts, records and backtests describe what the data and models show. They can be wrong, data can be late or missing, and the service can go down without warning.

Prediction markets carry a high risk of loss, including everything you put in. Any decision to trade is yours alone. Only use money you can afford to lose, and talk to a licensed professional if you want advice. BRAIN isn't affiliated with any prediction market, index provider or exchange.

TERM	MEANING
Line / target	The price the round is measured against.
Cushion	How far price is from the line right now.
Line cross	Price moving from one side of the line to the other.
Flow	Whether buyers or sellers are taking more volume across the exchanges.
Order-book wall	A large resting order that can slow price at a level.
Settlement average	The 60-second index average the round settles on.
Trend	The short-term direction: up, down or flat.
Spot	Where a round stands at a reading, used to compare it with similar past rounds.
Flip check	The rule for when the 8:00 reading may switch away from the 4:00 side.
Whale	A trade large enough to show up against normal volume (the size threshold adapts to the market).
Pass	Your access period to the live dashboard. Passes are one-time and never renew on their own.
